Physics behind Bus Rollover Bus rollover is a phenomenon in which the fully laden bus rolls about an axis parallel to the longitudinal direction of the bus passing through the outermost edge of the outermost tyre (Right/Left/Front/Rear) on ground. Bus rollover happens due to collision or high speed during cornering.

rollover/superstructure strength tests that conflict are the 49 CFR 571.216 and 571.220 (FMVSS roof crush resistance/school bus rollover protection) standards and the UNECE R-66 (superstructure strength) standard. The FMVSS standard is based on a quasi-static test, and the UNECE R-66 is based on a dynamic test.

The ECE R66 tilt table rollover was simulated using a full finite element model of the bus.

Numerical assessment of occupant responses during the bus

The FMVSS No. 220 test applies a uniformly distributed compressive load (equivalent to 1.5 times the unloaded vehicle weight of the bus), on the roof of the bus along its longitudinal centerline using a 915 mm (3 feet) wide platen that is 305 mm (1 foot) shorter than the bus length.

The Colorado Rack Test. In 1971, the Colorado Rack Test was implemented to help test the structural integrity of a school bus. If the school bus should rollover, the Colorado Rack Test ensures that the strength of the passenger cage is tough enough to withstand a rollover accident. For a school bus to be in compliance with the Colorado Rack Test, the structure of the bus cannot deflect more than 5? inches, and all emergency exits must still be operational.

This is a severe rollover test condition. The amplitude of the front wheel steering angle is set to 4°, the road adhesion coefficient is 0.85. In Figure 9, the triaxle bus will not be at risk of rollover at 60 km/h, 80 km/h and 100 km/h in the first phase of the Fishhook condition (before 3.5 s). In the second phase of the Fishhook condition, the bus rolls over at less than four seconds, with a speed of 100 km/h.
